

@MODERNDAY_LEONIDAS · THE ANNUAL PEPTIDE STACK · PART 2 OF 3

WHAT I ACTUALLY RUN, YEAR-ROUND

Two injectables. Two powders. The protocol nobody's affiliate code pays them to talk about.

LEONIDAS

WHAT I ACTUALLY RUN, YEAR-ROUND

You bought the supplement playbook. This is the upgrade.

The 3-supplement playbook — Creatine / Tongkat / Vitamin D3 — is the foundation. Everything in this stack sits on top of that foundation.

What's in here:

- Two injectable peptides I run year-round to keep my joints and tendons under repair.
- Two daily powders that fix what supplement marketing won't talk about — connective tissue and dairy-peptide protein synthesis.

This is what I actually run. Not what a clinic sells. Not what an influencer's affiliate code pays them for. The protocol, the doses, the off-cycle window, the brands. All of it.

⚠ BEFORE YOU READ ANOTHER SENTENCE

This is research-chemical and supplement protocol content. Peptides like BPC-157 and TB-500 are **not FDA-approved for human use** and are sold as research chemicals in the United States. You're responsible for understanding your local laws, your sourcing, and your own body. Nothing here is medical advice. **Talk to a doctor before injecting anything.** If you have a heart condition, an active cancer diagnosis, or any condition where tissue proliferation could be a problem, **do not run these peptides.**

You're an adult. Act like one.

BPC-157 — THE HEALING PEPTIDE

What it is: A 15-amino-acid sequence derived from a stomach protein (a pentadecapeptide). Studied extensively in animal models for tendon, ligament, gut, and joint repair. Used by lifters, fighters, and combat athletes for the nagging injuries that don't heal with rest alone.

What it does: Accelerates tissue repair via angiogenesis (new blood-vessel growth in injured tissue) and growth-factor upregulation. The effect on tendons and ligaments is the big one — they have notoriously poor blood supply and heal slowly without help.

HOW I DOSE IT

Reconstitute the vial with **300 units (3 mL) of bacteriostatic water** on a U-100 insulin syringe. Draw **30 units (0.30 mL) per dose** — that's one-tenth of the vial, so a vial lasts 10 doses. The actual milligrams per dose depend on your vial's strength: a **5 mg vial** $\approx$ **0.5 mg/dose**; a **10 mg vial** $\approx$ **1 mg/dose**. Confirm your vial and do the arithmetic before you draw.

Route: Subcutaneous (subq). I run subq. **When:** **30 minutes before training is ideal**, but timing isn't protocol-critical — any consistent slot works. Pick one you'll actually remember.

Cycle: This is a year-round peptide. I run it continuously, with the light off-cycle window covered below.

Why I run it: Lifting heavy for 15+ years catches up with your joints. BPC-157 keeps the small stuff — rotator cuff, knees, elbows, lower back — under continuous repair instead of letting it accumulate into a real injury.

Sourcing: Research-chemical territory. Look for vendors that publish third-party HPLC results. **DM me on Instagram for my contacts (research only).**

TB-500 (THYMOSIN BETA-4) — THE RECOVERY PEPTIDE

What it is: A 43-amino-acid peptide naturally produced by the thymus gland. It activates actin sequestering — helping cells migrate, repair, and regenerate tissue. Often stacked with BPC-157 because the two work on different repair mechanisms.

What it does: Accelerates muscle and connective-tissue recovery, increases cellular migration to injured areas, and helps with chronic inflammation and the slow-grinding overuse injuries that don't show up on an MRI but absolutely show up in your training log.

HOW I DOSE IT

I only run TB-500 **blended in the same vial as BPC-157** — same reconstitution, same **30-unit (0.30 mL) draw**, same schedule. The two come out of one syringe. **No separate loading phase** in my protocol; it runs as a continuous blend with BPC-157.

Route: Subq, same as the blend. Rotate sites to prevent irritation. When: Same draw, same timing as BPC-157 — 30 min pre-training ideal.

Off-cycle: Because it's blended, I take the injectables off together — roughly **3 weeks off about every 12 weeks**.

Why I run it: BPC-157 + TB-500 covers two repair pathways. BPC handles localized inflammation and angiogenesis; TB-500 handles cellular migration and the systemic side of tissue repair. Stacking them costs more than running either alone — and the recovery delta is real.

Sourcing: Same caveat as BPC-157 — third-party tested only. **DM me for my contacts (research only)**.

03

COLLAGEN PEPTIDES — THE CONNECTIVE-TISSUE FOUNDATION

What it is: Hydrolyzed collagen protein, broken into small bioavailable peptides. The bulk of the protein in your tendons, ligaments, skin, and joint cartilage *is* collagen — and most adults get nowhere near enough through diet.

What it does: Provides the substrate your body uses to rebuild connective tissue. Stack it with vitamin C for synthesis. There's real research-backed support for effects on joint pain, skin elasticity, gut-lining repair, and tendon thickness.

Dose: **Per the label** — most tubs land in the 10–20 g/day range. Run the manufacturer's recommended dose, mixed in liquid.

When: Morning coffee, midday water, or post-workout shake. **Consistency beats timing.**

Brand: Vital Proteins Original (blue lid) is the Amazon standard; Costco's Kirkland version is the cheapest decent option if you have a membership. Either works.

Why I run it: You can take all the BPC-157 in the world, but if you're not giving your body the raw amino-acid substrate to rebuild the tissue, you're working at half capacity. Collagen is the cheapest, most boring, most under-rated piece of this stack. **No cycling needed — run continuous.**

04

ISATORI BIO-GROW — THE DAIRY-PEPTIDE PROTEIN COMPLEX

What it is: A bio-active dairy-peptide concentrate from iSatori — not a whey, not a casein, but a separate class of milk-derived "bio-active peptides" made via proprietary processing. **iSatori markets it as an anabolic adjunct to your protein intake.**

What it does: Adds a dairy-peptide profile that supplements (not replaces) your regular protein. The manufacturer's claim is that the benefit comes from *anabolic peptide signaling* rather than simply topping off your amino-acid pool — treat that as a marketing claim, not settled science. Stack it into a shake or take it standalone.

Dose: **Per the label — dosed to bodyweight.** Check your current bottle; formulations change.

When: Most users stack it with a post-workout protein shake; standalone works too. Consistency matters more than timing.

Where to get it: Amazon, iSatori brand. Make sure you're getting the powder, not the bar.

Why I run it: This is the "what nobody talks about" piece. Most protein guidance ends at whey + casein. Bio-Grow adds a third class of dairy peptides. Cost-to-benefit is favorable *if* you're already nailing the basics — eating enough, lifting hard, sleeping. **No cycling needed — run continuous.**

THE EXACT STACK

COMPOUND	DOSE	FREQUENCY	OFF-CYCLE	COST/MO
BPC-157	30 units (0.30 mL) from a vial reconstituted with 300 units (3 mL) BAC water (≈ 0.5 mg/dose at 5 mg/vial)	Daily — 30 min pre-training ideal	Light (see window)	\$50–80
TB-500	Blended with BPC-157; same 30-unit draw, one syringe	Daily (blended)	~3 wks off every ~12 wks	\$80–120
Collagen Peptides	Per label (10–20 g)	Daily	No cycling	\$20–35
iSatori Bio-Grow	Per label (dosed to bodyweight)	Daily	No cycling	\$40–60
Total				~\$190–295/ mo

OFF-CYCLE WINDOW

Here's the honest version: I don't see a real need to cycle off, beyond keeping yourself in check. What I actually do — and what I'd tell you to do — is one of two light approaches:

- ~3 weeks off at a time of your choosing, or
- 4 days off once every ~2 months.

That's it. The injectables — the BPC-157 / TB-500 blend — come off together during the break. **Collagen and Bio-Grow stay on**; they're food-grade and don't need cycling.

THE REAL REASON

It isn't some elaborate receptor-reset theory. It's discipline: **don't abuse your tools. Dose mildly.** Your nutrition and your training are what actually build the body — the peptides just keep the repair side from falling behind. I didn't know what protein even was until I benched 300 lbs at 17. The basics did that. The basics still do most of the work.

And the caveat that actually matters: **run anything you're unsure about past your doctor (or your own AI agent) first.** Your body, your call, your liability.

RUNNING THE STACK — PRACTICAL NOTES

Storage. Reconstituted peptides go in the fridge. Lyophilized (powder, pre-reconstitution) peptides go in the freezer for long-term storage, or the fridge if you'll use them within 30 days.

Reconstitution. Bacteriostatic water (BAC water), not saline. My vials get **300 units (3 mL)** of BAC water; I draw **30 units (0.30 mL)** per dose. Quick arithmetic to memorize: **mg per dose = vial strength $\div$ 10** (a 5 mg vial $\rightarrow$ 0.5 mg/dose; a 10 mg vial $\rightarrow$ 1 mg/dose).

Syringes. Insulin syringes, U-100, 29–31 gauge. Subq in the abdomen, rotate the site.

Schedule discipline. Set a phone reminder for injection days. If you miss a dose, skip it — don't double up.

Stack with the basics. This assumes you're already running creatine, Tongkat Ali, and vitamin D3 per the free supplement playbook. If you're not running the basics, fix that first — peptides amplify a working foundation, not a missing one.

Disclaimer. Not medical advice. Not an endorsement of unregulated research chemicals for human use. Peptides like BPC-157 and TB-500 are not FDA-approved for human consumption in the United States. Sourcing, possession, and use are your responsibility under your local laws. Consult a doctor before starting any peptide protocol — especially if you have a pre-existing condition, take prescription medications, or have any history of cancer. This document represents one operator's personal protocol. Your body, your decision, your liability.
